

Lab 1

Intro:

I started by following the steps on Canvas and flashing the sd card, soldering the required pins onto the Pi and making the LED blink

Steps

1. I started by soldering the pins onto the Pi that went pretty much like any good story.

2. the card flashing went not so good. I put in the wrong PW and have had to deal with the consequences. I setup the Pi but ~~now~~ now I have to re-flash the card.

2a) Flashing the card. I chose the OS Raspberry Pi zero and chose Pi OS Lite. Picked Hostname FridayPi + inspired by Iron-man. then I enabled raspberry Pi Connect for Debugging purposes. First Boot after re-flash.

Host is up!! I can see it with an nmap scan.

'Sudo nmap "10.98.208.1/24" -p 22 -T3' Shows Host name FridayPi but when I try my ssh key it denies the fucking key!!

Trying debugging steps. The Pi Connect works but ssh fails... manually adding ~/.ssh/authorized-keys did not work.

10/11

Lab 1Debugging Connecting

first after trying to connect with SSH and failing for about 45 min I realize I'm a dumbass and forgot to add 'Sverris' in front of the @ So I was doing 'ssh 10.98.208.51' instead of 'ssh Sverris@10.98.208.51' Then I finally get a new error: Public key decayed... ARE YOU KIDDING ME?? fixed the ~/.ssh/permissions. Still failed... Ran 'ssh -vvv' → key was being offered. So issue was not that.

Turns out It was offering the wrong key!! fixed that by adding it to * in SSH Config... Now connecting with 'ssh Sverris@10.98.208.51' works! but since that IP rotates I wanted to use the hostname but host name would not resolve so after having my friend nmap the network and seeing that ~~it~~ it was resolving for him I knew the problem was on my DNS, and it was Cloudflare DNS had taken over so after fixing the resolver it STILL did NOT resolve... Turns out FridgePi.local does not work. I have to use .ru.local so then it resolves and I can connect via host name.

Time of Start - 16:00

Time of finish - 19:00

Making The LED blink...

Put the Python Script on the Pi and connected the minus to Physical Pin number 15 and the ground ~~to~~ to Physical Pin number 6 and made a circuit on the Bread board. Connected Pi's to 12a on the board then the + of the LED to 12e and - to 14e then the ground to 14a... in the middle was a 1kΩ resistor. This went smoothly.

Main

Lab 1:

Conclusion

Soldering was easy since I have done that before. Then flashing was a rough journey but managed after about 2 hours of debugging. Then making the circuit and having the light blink was smooth.
